

Week 2

Box Model- Hand-Built MODFLOW

Diana, Adam, Jake

The Challenge #1

Create a conceptual model of the homogenous MODFLOW model: This should be an illustration that shows the locations and values of constant head boundaries, the number of grid cells and their spacing as well as any other model properties. You should also include in here a cross section with your predicted head gradient and direction of flow. You can draw this by hand if you would like.

Hydraulic Head Gradient = dH/dl

$(15\text{m} - 10\text{m})/(0-2500\text{m})$

$dH/dl = -0.002$

$q = -K (dH/dl) ; K = 1\text{m/d}$

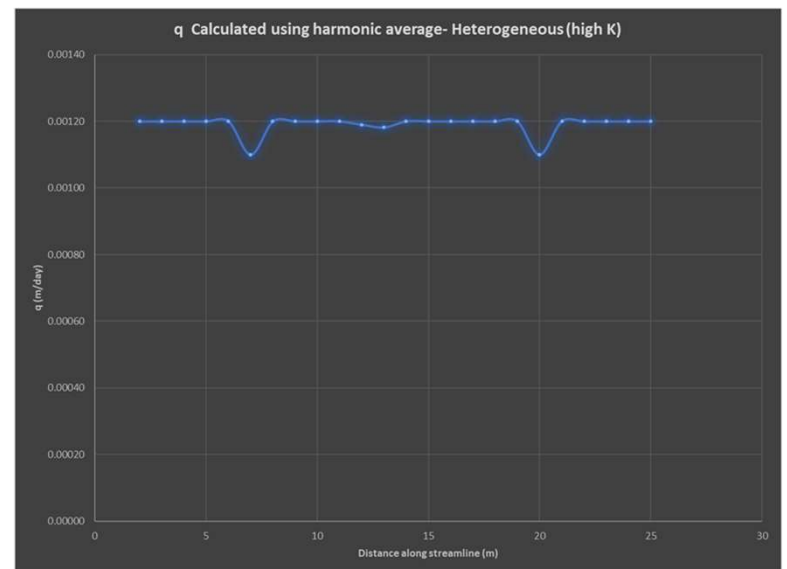

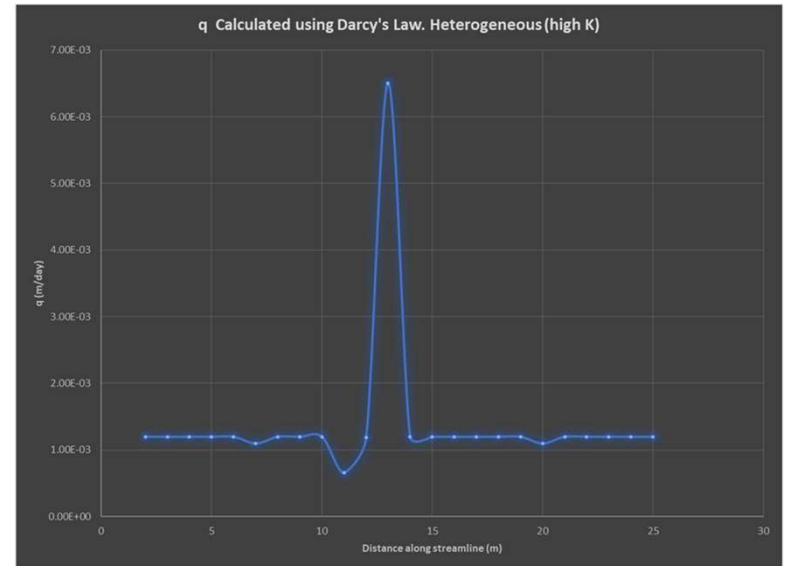

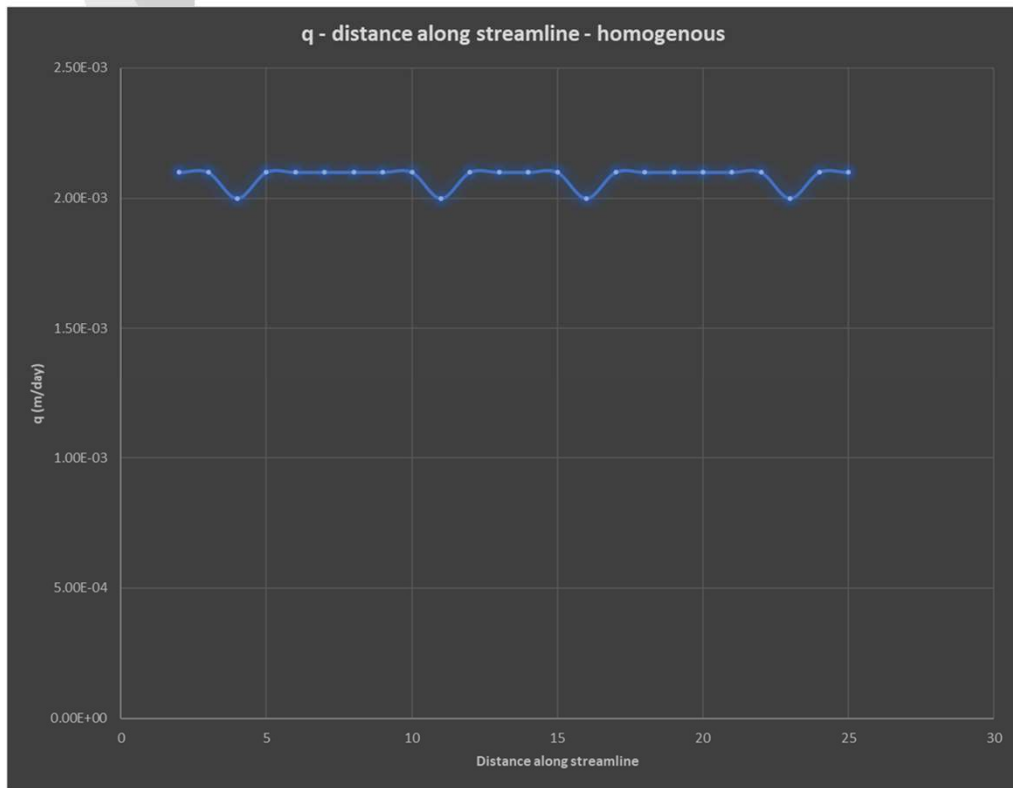

$q = 0.002 \text{ m/d}$

The Challenge #2

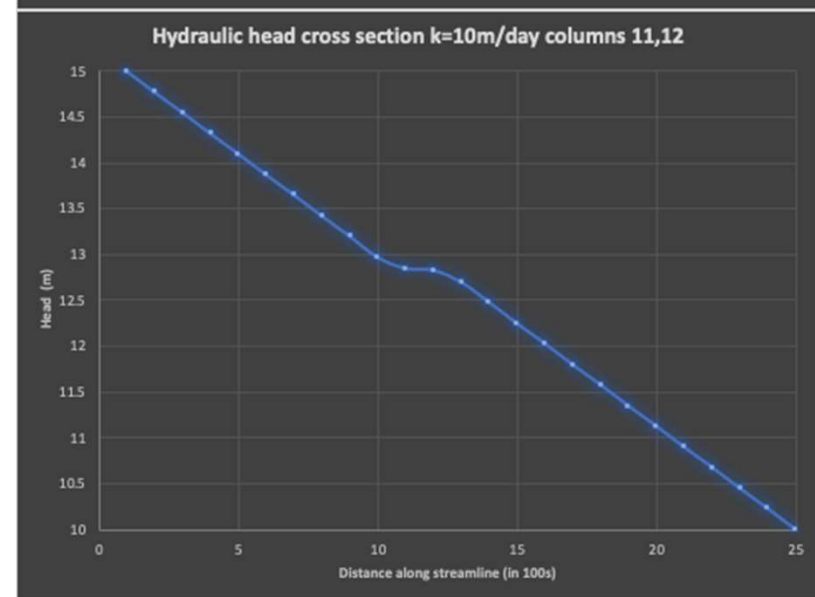

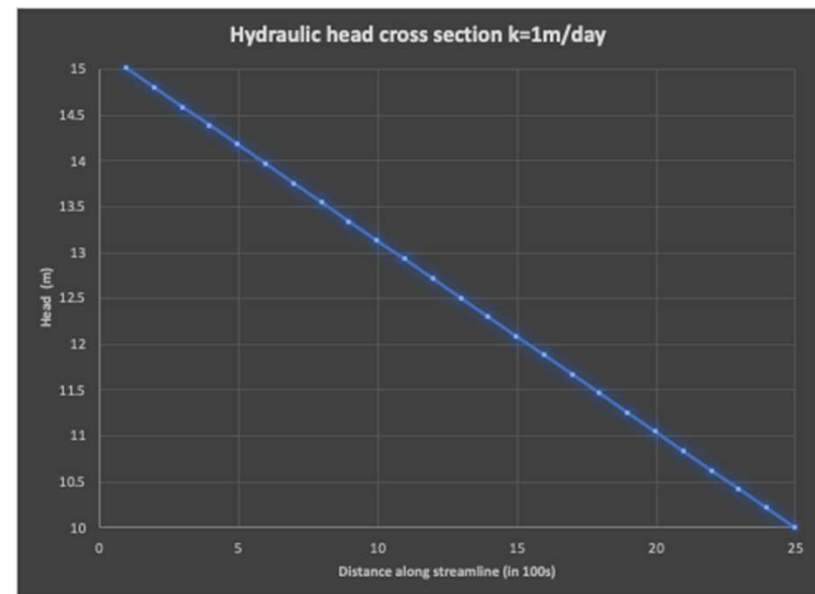

Show, based on the flux with horizontal distance from a constant head boundary, that the model is steady state. Repeat this for a homogenous and a heterogenous cases where you place different K values in series in the direction of flow (Note: to modify the K values you should change the .bcf file, just be careful because spacing matters! Note 2: see the excel sheet for an example calculating flux. Keep in mind that that heads are calculated at the center of a cell and the K values are defined across the entirety of a cell)

The Challenge #3

Show the steady state head contour in plan view for the homogeneous and heterogeneous (zones in series) condition. Use this plot to defend a contention that flow is 1D. Then, drawing on your first assignment, use the results to explain WHY the equivalent hydraulic conductivity, K_{eq} , is closer to the lower of the two K values.

How is flow 1D?

- Assume no flow y or z direction
- Saturated conditions
- Dimensional analysis

Modflow output = no change in head values in the y direction, only along the (x) horizontal direction. The z layer is only 1 unit deep so no flow is possible

		1	2	3	4
		0	100	200	300
1	0	15	14.79	14.58	14.38
2	100	15	14.79	14.58	14.38
3	200	15	14.79	14.58	14.38
4	300	15	14.79	14.58	14.38
5	400	15	14.79	14.58	14.38

22	2100	15	14.79	14.58	14.38
23	2200	15	14.79	14.58	14.38
24	2300	15	14.79	14.58	14.38
25	2400	15	14.79	14.58	14.38

SPECIFIC DISCHARGE, FLUX

$$q = \frac{Q}{A} \quad Q = L^3/T \quad A = L^2$$

$$q = \frac{L^3/T}{L^2} = \frac{L}{T} \quad \checkmark$$

$$q = -K \frac{dh}{dL} \quad -K = \frac{L}{T} \quad dL = L \quad q = \frac{L}{T}$$

$$dh = \frac{q \cdot dL}{-K} = \frac{\cancel{\frac{L}{T}} \cdot L}{\cancel{\frac{L}{T}}}$$

$$dh = L = 10$$

Use the results to explain WHY the equivalent hydraulic conductivity, K_{eq} , is closer to the lower of the two K values.

Using a simple scenario we can illustrate how smaller k values influence the overall value of K_{eq} to be skewed towards the smaller k value.

Consider a model with 20 cells, there are 10 cells with k value = 10 and 10 cells where $k = .1$. To calculate K_{eq} we use this harmonic average

$$H = \frac{n}{\frac{1}{x_1} + \frac{1}{x_2} + \dots + \frac{1}{x_n}} = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}} = \left(\frac{\sum_{i=1}^n x_i^{-1}}{n} \right)^{-1}$$

$$20 / ((10/10) + (10/.1)) = 20 / ((1 + 100)) = K_{eq} = 0.198$$

A more extreme example where only one cell out of 20 = .1 :

$$20 / ((19/10) + (1/.1)) = 20 / ((1.9 + 10)) = K_{eq} = 1.68$$

The Challenge #4

Build a model based on a homogeneous domain with a square region of lower K in the middle of the domain. What can you learn based on your explanation of what controls the effective K for a 1D flow system now that you are applying it to a 2D system? What do you think the K_{eq} of this entire system would be compared to the high and low K values? Explain why it is much more difficult to develop a direct solution for this 2D system than it was for a 1D system (including the zones placed in series).

What can you learn based on your explanation of what controls the effective K for a 1D flow system now that you are applying it to a 2D system? What do you think the K_{eq} of this entire system would be compared to the high and low K values?

For Discussion

It's possible K_{eq} would skew towards the high K value when we create a square blockage.

[illegible]

Physical Properties and Principles / Ch. 2

Figure 1.1: An illustration of anisotropy and heterogeneity (Ikelle & Amundsen, 2005)

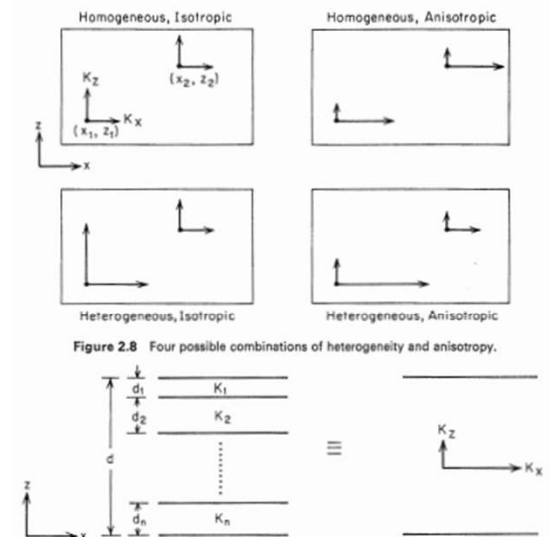

Figure 2.9 Relation between layered heterogeneity and anisotropy.

Explain why it is much more difficult to develop a direct solution for this 2D system than it was for a 1D system (including the zones placed in series).

Consider an arbitrary flowline in the xz plane in a homogeneous, anisotropic medium with principal hydraulic conductivities K_x and K_z [Figure 2.10(a)]. Along

Figure 2.10 (a) Specific discharge v_s in an arbitrary direction of flow.
(b) Hydraulic conductivity ellipse.

the flowline

$$v_s = -K_s \frac{\partial h}{\partial s} \quad (2.35)$$

where K_s is unknown, although it presumably lies in the range $K_x - K_z$. We can separate v_s into its components v_x and v_z , where

$$v_x = -K_x \frac{\partial h}{\partial x} = v_s \cos \theta \quad (2.36)$$

$$v_z = -K_z \frac{\partial h}{\partial z} = v_s \sin \theta$$

Now, since $h = h(x, z)$,

$$\frac{\partial h}{\partial s} = \frac{\partial h}{\partial x} \cdot \frac{\partial x}{\partial s} + \frac{\partial h}{\partial z} \cdot \frac{\partial z}{\partial s} \quad (2.37)$$

Geometrically, $\partial x / \partial s = \cos \theta$ and $\partial z / \partial s = \sin \theta$. Substituting these relationships together with Eqs. (2.35) and (2.36) in Eq. (2.37) and simplifying yields

$$\frac{1}{K_s} = \frac{\cos^2 \theta}{K_x} + \frac{\sin^2 \theta}{K_z} \quad (2.38)$$

This equation relates the principal conductivity components K_x and K_z to the resultant K_s in any angular direction θ . If we put Eq. (2.38) into rectangular coordinates by setting $x = r \cos \theta$ and $z = r \sin \theta$, we get

$$\frac{r^2}{K_s} = \frac{x^2}{K_x} + \frac{z^2}{K_z} \quad (2.39)$$

There is more to account for in 2D, leading to more difficulty for calculating direct solutions

The Challenge #5

For steady state conditions, there are equivalent Type I and Type II boundary conditions. What would the Type II boundary condition be that would result in the same equipotentials for the first model? What is the value of the constant flux? What about the second model? What are the values of the constant flux on the left and right boundaries? What is fundamentally different about the equivalent Type II boundary for the third model compared to the first two?

1st Model

-Constant flux boundaries on both sides would produce the same equipotential profile as the constant head boundary condition run of our model

The left and right q values would both be 2.1 E-3 m/day

2nd Model

-Constant flux would also produce the same equipotential profile in this case, however the flux needed will differ from the 1st model, but remains identical on both the left and right.

The left and right q value would both be 1.2 E-3 m/day for higher K layer scenario

3rd Model

-Constant flux would work in this case as well, but depending on where the profile is taken in the model space, the left and right boundary may not have the same constant flux

If taken through the center of the square, $q_{\text{left}} = 5 \text{ E-4 m/day}$, $q_{\text{right}} = 1.5 \text{ E-3 m/day}$

If taken through the edge of our model area, q becomes 2.1 E-3 on both sides, just as in the homogenous case

Glossary – Jake Smith

1. MODFLOW is a groundwater modeling program based on the python programming language. It is a grid based model.

There are many MODFLOW packages, which each add a unique component to existing models, like a evapotranspiration package, or a river package.

Th inputs to our mudflow models were hydraulic conductivity, and various values input into the .dis file that set the physical bounds/grid settings to our project. This includes dimensions and boundary conditions.

Glossary

2. Hydraulic conductivity and head gradient have an inverse relationship. This can be gleaned by looking at Darcy's Law $q = -K \frac{dh}{dz}$. For q to remain constant at a point, k and h have to inversely to change.

Glossary

3. A model node is the point where model calculations take place. They can also serve as observation points in software like Hydrus. A cell is one of the grid elements within MODFLOW. The cells are bounded by nodes on the borders of cells.

Glossary

4. Type 1 conditions are constant head, while type 2 conditions are constant flux. Constant head is useful in situations where you have an effectively unlimited reservoir of water on the timescale of your model. Ex. like a large lake. Constant flux is useful in situations where you may already know information about how much flow is going through a model area and could be useful in modeling infiltration or recharge.
